FOREWORD

This is the first of two publications dealing with migration in Lousiana from 1970 to 1980. It describes the patterns of migration over the decade for Louisiana, economic regions, central city parishes, metropolitan rings, nonmetropolitan fringes, and individual parishes. Whenever possible, comparisons are made with earlier periods.

Volume 2 presents the detailed net migration tables from which this analysis stemmed. The data include figures by age, race, and sex for the state, each parish, each State Planning District, each multiparish metropolitan area, each economic region, and the component subregions of each economic region.

Both publications are available from the Division of Business and Economic Research, University of New Orleans, New Orleans, Louisiana, 70148, telephone (504) 286-6248.

The authors wish to acknowledge the invaluable assistance of Dr. Jerry P. Simpson, Raul Fletes, Stott Atkinson, Michael Hall, Dorothy Dantzler, and Donna Smith of the Division of Business and Economic Research; Dr. John Wildgen of the Political Science Department; and Sandra Furlan of the Office of Publications. In addition, we appreciate the use of the facilities and support of the staff of the Computer Research Center of the University of New Orleans. Without this help, our task would have been impossible.

Chapter 1

INTRODUCTION

For the first decade in recent times, the 1970s was a period of net inmigration into Louisiana. In fact, this net inmigration was greater than for any other decade in measurable history going back more than a century. Further analysis reveals the sources of the change--an increase in white/other races' net inmigration, coupled with a decrease in black net outmigration. These and other points will be highlighted in this study.

Background of Study

This report updates Migration in Louisiana, 1960-1970 by Georgios C. Christou, published in 1973 as Research Study Number 17 by the Division of Business and Economic Research of the University of New Orleans. Data from that monograph were used extensively in making comparisons between the two decades.

Gross migration flows (in and out) are the optimal data to employ to obtain a complete depiction of population changes, but they are generally not available in detail for small areas such as parishes. Therefore our discussion will concentrate on net migration (in minus out).

The net migration data presented here were generated to provide vital input into the set of population projections recently prepared by the Division of Business and Economic Research of the University of New Orleans and the Louisiana State Planning Office. The use of migration in the cohort-component model is detailed in Population Projections to 2000 for Louisiana by Age, Sex, and Race and for Louisiana Parishes by Race and Sex, Series I Report, by Vincent Maruggi and Raul Fletes, released in June, 1983. Because migration is such an important component, it merited further examination.

Migration is an important demographic factor to trace. Its patterns and trends are valuable tools for business, government, and civic planners. As fertility and mortality components approach near-replacement levels, migration becomes more important in determining population change. Additionally, it has been found that:

> In the relatively short run, migration has economic significance mainly in that it provides the most important avenue by which the supply of labor may be adjusted to the existing demand. Over a somewhat longer span of time the process of migration has further economic significance in that it modifies not only the supply of labor in a given market but also the demand for labor as well.[1]

Migration in Perspective

Migration of population generally reflects the migrants' perceived economic and social opportunities in the area of destination relative to their area of origin. Job-related (economic) factors have been shown to overshadow people-related (social) factors as the major causes of migration between different areas. Migration is a function of both "push" and "pull" forces. The push is generally characterized as the lack of economic opportunities in the sending area, and the pull by the relative presence of economic opportunities in the receiving area. A migration study is consequently a study of the competitive economic advantages of different regions for the specific migrating populations.

Migration is not a one-directional phenomenon. A flow of migrants from one area to another is likely to be accompanied by a counter flow in the reverse direction. Taken independently, these flows constitute gross migration. Taken together, they somewhat offset one another to

yield net migration. Or, in other words, net migration is the difference between the number of people moving into and out of a given area. An area has positive net migration (net inmigration) when more people move into the area than move out. Conversely, as area has negative net migration (net outmigration) when more people move out than move in.

Generally speaking, the smaller the geographical area, the greater the impact of migration on population dynamics. For very small areas, wide fluctuations over time are common.

Many socioeconomic variables influence a person's decision to migrate--such as age, race, sex, marital status, income, occupation, urban/rural residence, and region of the country. Unfortunately, the degree to which each of the above factors affects migration is not uniform and predictable. Therefore one blanket hypothesis cannot account for all the reasons for migration of the population, but generalized hypotheses can be researched about individual influences or combinations of individual influences.

Some people are far more prone to migrate than others. The most conspicuous differences in migration rates are those experienced by an individual passing through successive stages of life. These changes are rather similar for the two sexes; for simplicity's sake, we describe them here in terms of a male.

> As a very young child, he is relatively portable. After he enters school and has older, more settled parents (and probably more brothers or sisters), his probability of moving declines. The rate rises suddenly when he is ready to look for a job or choose a college, and it remains high until after he is married and has children of his own. As his stakes in his job and in his community grow, and as his and his family's local ties develop, he becomes less likely to move. His mobility recovers somewhat at the stage when all of his children are on their own, and again at the customary mid-sixties retirement

> age. After about seventy, migration rates tends to rise a little, presumably reflecting adjustments to death of the spouse or to growing incapacity.[2]

Migration tends to be concentrated in the "young adult" age groups. These individuals are in the career-starting and primary reproduction ages. Migration therefore affects not only the population in these age groups but also their children in the very young age groups.

Other patterns of migration have been found concerning its impact on the area of origin and of destination. A significant conclusion concerning urban to urban migration is: "These findings suggest (1) that migrants (except from rural areas) tend to be superior to the population of the destination area as well as the origin area, and (2) that selectivity may be increasing."[3]

Chapter 2

METHODOLOGY

The best benchmark data which may be used to compute residual net migration came from the decennial Census of Population and raw vital statistics figures from the Louisiana Department of Health and Human Resources. The detailed data used in estimating residual net migration in this study are by race, sex, and age.

We developed software to produce this level of migration detail for each parish. It uses Census enumerations together with Health and Human Resources intercensal births and deaths to calculate migration as a residual. By applying decennial births and deaths to the 1970 base population, we computed the number of survivors in 1980 by age, race, and sex. The residual difference between the 1980 Census count and the 1980 survivors was net migration.

However, direct application of this method was problematic. The sizeable Census undercount in 1970 and subsequent reduction in the undercount in 1980 rendered the counts incomparable. Based upon this fact, we produced three estimates of net migration from the period 1970 to 1980.

Low, Middle, and High Migration Estimates

It is recognized that the 1980 Census contained considerably less undercount than the 1970 enumeration. To estimate net migration, it was necessary to develop an approach which took this fact into account. Consequently we developed alternative estimates of 1970-1980 net migration based upon different 1970 base population figures.

The first approach used 1970 Census population counts to derive migration. Since there was a reduction of undercount between Censuses, there is a sizable number of persons enumerated in 1980 who were not counted in 1970, and these people would have been included in the calculations of residual net migration. Therefore this first set of migration figures were considered "high."

The second approach adjusted the 1970 population by applying the estimated national age, race, sex-specific undercount rates in 1970 to obtain a "true" population for each parish for that base year.[4] The counts for 1980 were assumed to be complete (i.e., no undercount). Since the 1980 Census did contain some undetermined amount of undercount, there are individuals who would have been included in the "true" 1970 population that were not included in the 1980 count or in the net migration calculation, and these would have had the effect of reducing the residual population which is net migration. Therefore this migration series was labeled "low."

Another estimate of residual net migration was obtained by averaging the high and the low estimates. The implicit assumption resulting from averaging is that, in absolute terms, the 1980 Census undercount by race, sex, and five-year age group was exactly one-half of the corresponding 1970 Census undercount. These figures are the "middle" estimates, which are considered to be the most likely estimates of migration over the decade. It is this middle estimated series which is presented and discussed in this paper.

---

[4]"Special" populations whose enumerations were complete were not adjusted. Special populations in three parishes were delineated--Claiborne, which houses the Wade Correctional Institution, Vernon, which contains Fort Polk, and West Feliciana, which includes the Angola Correctional Institute. These areas were given special treatment in adjusting for undercounts in 1970.

This technique of estimating residual net migration has inherent advantages over other methods. First, it employs actual vital statistics births and deaths data supplied by the Louisiana Department of Health and Human Resources, Office of Health Services and Environmental Quality. Some other techniques employ fertility and mortality/survival rates to estimate births and deaths over the period. To apply the latter method requires estimating these rates for the interval. It is quite possible that unexpected changes in fertility and/or mortality could have occurred that render those rates unusable. In addition, in some parishes individual cohorts may be so small that the estimated rates may not be applicable.

Second, the problem of differential coverage in Censuses can be handled using actual data. In the past, the Census Bureau had developed a set of national age/race/sex-specific 10-year survival rates that account for differential Census coverage. At present similar rates are not available for the 1970-1980 period and it is not known whether they will be developed at all. Even if they were available, it is unsure whether they would have enhanced the accuracy of the estimates. Therefore we feel confident that, given the limitations in data available, our approach is the most sound one to use.

Race Categorization Change

A problem arose as a result of the 1980 Census data. The race characteristics reported by respondents were not obtained in the same manner as in previous Censuses. In fact, the Census Bureau cautions against making direct comparisons between 1980 and previous Census years' figures. Consequently we changed the race groupings for which the migration analyses were to be made. Instead of using, as in the past, a white/nonwhite breakdown, we now group the white and "other" races together and separate out the black race. The implicit assumption for this set of categories is that the "other" races more closely resemble whites than blacks in the trends of migration. This change was necessitated by the difference in self perception of race

by persons of Spanish origin. A larger proportion of the Spanish origin population in 1980 than in 1970 reported their race as "other." In addition, in 1970 most persons who did not classify themselves in a special race category but who instead wrote in a Spanish designation such as Mexican, Cuban, Puerto Rican, Dominican, Nicaraguan, Latino, etc. were classified as white. In 1980 these same people were classified as "other." Only the black racial identification (termed Negro in previous Censuses) has remained consistent. Therefore the white/other and black dichotomy is actually quite similar to the former white and nonwhite breakdown.

Analysis of net migration in the 1970s will be somewhat affected by this categorical change. However, the impact is expected to be minimal.

Statistical Procedure

Net migration for five-year age/race/sex cohorts from 1970 to 1980 is estimated as a residual according to the following equation.

$$M_{i,r,s} = P^{80}_{i,r,s} - P^{70}_{i-2,r,s} - (B_{i,r,s} - D_{i,r,s})$$

where:

$M_{i,r,s}$ = net migration from 1970 to 1980 for the 5-year age cohort i in 1980 of race r and sex s

$P^{80}_{i,r,s}$ = population in 1980 of 5-year age group i of race r and sex s

$P^{70}_{i-2,r,s}$ = population in 1970 of 5-year age group i-2 of race r and sex s

$B_{i,r,s}$ = number of births from 1970 to 1980 for the 5-year age group i in 1980 of race r and sex s

$D_{i,r,s}$ = number of deaths from 1970 to 1980 for the 5-year age group i in 1980 of race r and sex s

To utilize this approach, births and deaths must be calculated in terms of 1980 age groups. The formulae to aggregate births are:

$$\text{For } i=1 \quad B_{i,r,s} = \sum_{Y=1976}^{1980} B_{y,r,s}$$

$$\text{For } i=2 \quad B_{i,r,s} = \sum_{Y=1971}^{1975} B_{y,r,s}$$

$$\text{For } i=3,18 \quad B_{i,r,s} = 0$$

where: $B_{y,r,s}$ = number of birth in year y of race r and sex s.

Over a ten-year period, births impact only the two youngest cohorts. Therefore for all older groups, births equal zero.

To estimate deaths in terms of 1980 age groups, the following equations were employed:

$$D_{i,r,s} = \sum_{j=5i-5}^{5i-1} D_{j,r,5} \quad \text{for } i=1,17$$

$$D_{i,r,s} = \sum_{j=85}^{\text{Max } j} D_{j,r,5} \quad \text{for } i=18$$

where: $D_{j,r,s}$ = number of deaths of single-year age j in 1980 of race r and sex s

Yet $D_{j,r,s}$, the number of deaths of race r and sex s for people who would have been age j in 1980 had they survived, cannot be directly obtained from the raw data. Instead, estimates of these

deaths were made utilizing the year of death and the age at death for each individual. Therefore j, the age in 1980 had the individual survived, was calculated by the following formula:

$$j = a + (1980-y)$$

where: a = age at death
y = year of death

Since all of the variables on the right-hand side of Equation 1 are now now in place, residual net migration can be calculated.

As a rate, net migration is traditionally expressed relative to those who are at liberty to move. It is computed as the number of net migrants over the period divided by the number of survivors in the terminal year. The following formula calculates migration rates:

$$m_{i,r,s} = \frac{M_{i,r,s}}{S_{i,r,s}}$$

where: $m_{i,r,s}$ = net migration rate from 1970 to 1980 for the 5-year age group i in 1980 of race r and sex s

$S_{i,r,s}$ = Survivors in 1980 of 5-year age group i of race r and sex s

The number of survivors in the terminal year can be computed from the population in the beginning year and births and deaths by employing the following formula.

$$S_{i,r,s} = {}^{70}p_{i-2,r,s} + B_{i,r,s} - D_{i,r,s}$$

Chapter 3

LOUISIANA GROSS MIGRATION

Gross migration data by state become available as a by-product of the decennial Census of Population. Tables 1 and 2 present the interstate gross migration flows from the past two Censuses. However, those figures are not comparable in nature to the residual net migration calculated through the procedure described in Chapter 2. The Census reports migration between states over a five year span for all persons alive at both the beginning and the end of the period, largely disregarding movements to and from abroad. Our net migration estimates pertain to a 10 year period and include persons of all ages, even those who were born during the decade. While the two series are not directly comparable, they still reflect the same overall major trends in migration. Therefore analyzing gross migration will help in understanding net migration.

The most striking change between the 1965-1970 and the 1975-1980 interstate gross migration figures concerns the net figures which they yield. The latter period showed a net inmigration to Louisiana of 46,550 persons from the other 49 states and the District of Columbia; in contrast, the former period showed a net outmigration from Louisiana of 38,753 people. This phenomenon is almost solely due to an increase of nearly 89,000 inmigrants from 1965-1970 to 1975-1980, while the outmigration remained fairly constant between the periods (+ 3066).

In both periods, Louisiana received net inmigration from the Northeast and North Central regions. However, the 1975-1980 period exhibited dramatic increases in the net import of people from those areas. While Louisiana has continued to be a net exporter of migrants to the West region, the number of net outmigrants has fallen off

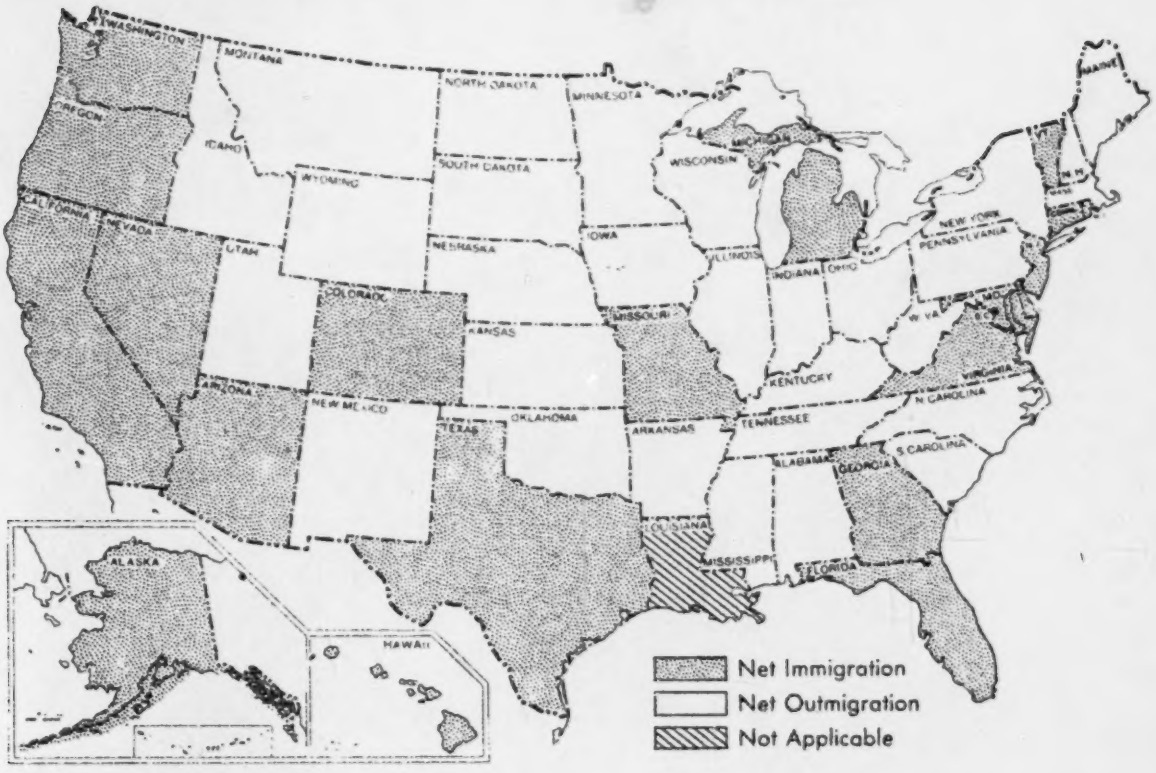
sharply in recent years. A change occurred within the South region with respect to Louisiana interstate migration. The 1975-1980 span showed a net inmigration into the state while the earlier period revealed just the opposite. This fact can be partially attributed to the increase in petroleum drilling activities in and offshore Louisiana which attracted workers from several neighboring states for its labor force.

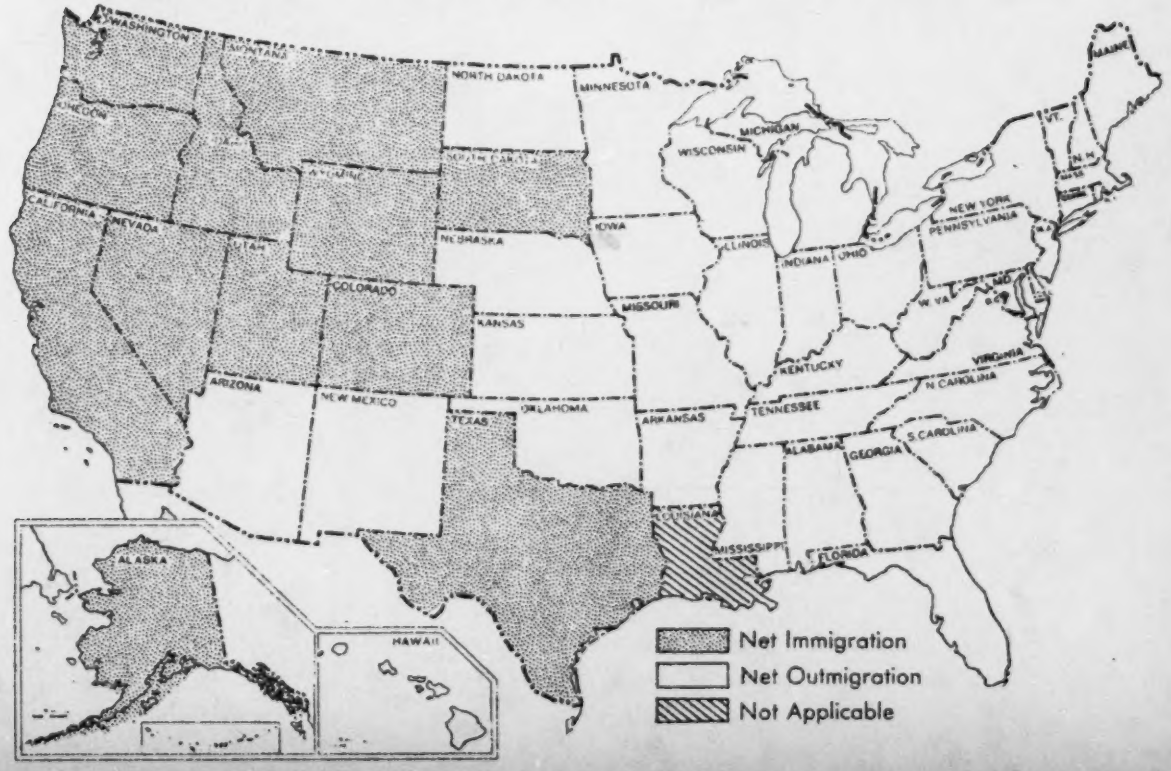
Maps 1 and 2 exhibit the interstate migration patterns to and from Louisiana during 1965-1970 and 1975-1980. It can be readily seen that, in the former period, Louisianians generally migrated to Texas, the western states, and a checkerboard of largely industrialized states east of the Mississippi River. However, from 1975 to 1980 this pattern changed. Nearly all the net outmigrants from Louisiana settled in the West. In fact, almost all the western states received net outmigrants from Louisiana. With the single exception of the District of Columbia, all the states in the east contributed net inmigration into the state. This fact can be partially attributed to the waning economic opportunities in the industrialized Northeast and North Central regions, coupled with the recent growth in the Louisiana economy.

These gross migration data show that migration is, indeed, a two-way street. In both periods the top five ranking states in sending migrants into Louisiana have also been the top five ranking states in receiving migrants from Louisiana. These five are, in rank order: Texas, Mississippi, California, Florida, and Arkansas. Collectively, they account for approximately 50% of the total inmigrants into and nearly 60% of the outmigrants out of Louisiana.

MAP 1 INTERSTATE NET MIGRATION TO AND FROM LOUISIANA, 1965-1970



MAP 2 INTERSTATE NET MIGRATION TO AND FROM LOUISIANA, 1975-1980



Note that three of the states listed above share boundaries with Louisiana. This fact is consistent with the traditional expectations "that contiguous areas will be the loci of considerable cross movement of population."[5] Analysis reveals a consistent pattern of large net outmigration to Texas and slight net inmigration from Arkansas and Mississippi despite the relatively large number of migrants between Louisiana and the latter two states. This reflects the extensive industrial development which has taken place in Texas and the continued lack of comparative economic opportunities in Mississippi and Arkansas.

One step further along this theory implies that it is reasonable to expect the largest interstate migration flows into and out of Louisiana to occur within the region in which the state is located. Indeed, the South did account for over 60% of both the inmigration to and outmigration from the state for both the 1965-1970 and 1975-1980 periods.

The net migration figures for states from these gross migration data reveal a contrast from the late 1960s to the late 1970s. The only constant is that Texas has continued to be the leading state in receiving net migrants from Louisiana. The amount of net migration to Texas from Louisiana has also remained fairly steady (21,479 persons in the first period, 20,787 persons in the second). California and Washington also continued to be major draws of net migration from Louisiana, but in decreasing numbers. Over 1965-1970 these two states ranked second and third, respectively, in the receipt of net migrants from Louisiana. Their rankings were reversed in the latter period, 1975-1980.

---

[5] Tommy W. Rogers and Lyndon E. Dawson, "Louisiana-Mississippi Migration Exchange," The Louisiana Economy, Research Division, College of Administration and Business, Louisiana Tech University, August, 1978, p. 8.

Nearly opposite observations were made regarding net inmigration into Louisiana from other states. Only New York ranked in both periods in the leading five sending states of net migrants to Louisiana--fourth in 1965-1970, second in 1975-1980. The focus of net migration also shifted from a few selected southern states to the entire north in general.

In summary, with the exclusion of Texas, not only have fewer states been receiving net migrants from Louisiana, but the ones that still are are receiving less. In contrast, more states are sending more net migrants to Louisiana.

The above analysis disregards migration to and from abroad. This is because the (domestic) Census cannot possibly reach those people who have moved out of the country to determine destinations and their origins five years earlier. However, it does enumerate people who have moved in from foreign countries. From 1975 to 1980, 43,752 persons migrated into Louisiana from abroad compared to 26,042 persons from 1965 to 1970. This increase is largely due to the resettlement of Vietnamese into the state since 1975. While no figures are available from the 1970 Census regarding Vietnamese in Louisiana, it is expected that nearly all of the 10,884 whom the 1980 Census recorded as residing in the state in 1980 arrived during the previous five-year span.

Chapter 4

LOUISIANA NET MIGRATION

The decade of the 1970s brought into Louisiana the greatest amount of net inmigration that has ever been recorded. From 1970 to 1980, some 126,007 more people moved into the state than moved out. This fact is consistent with the findings of the gross migration analysis. In contrast, the state lost 106,811 persons through net outmigration in the 1960s. The gross migration data suggest that an increase in inmigration rather than a decrease in outmigration accounts for the shift.

Several factors can be cited for the reversal of Louisiana's lengthy trend of net outmigration. Louisiana is situated in the middle of the Sunbelt, which, as a whole, has been the draw for the majority of the interstate net inmigration. In addition, the Louisiana economy of the 1970s was strong enough to pull residents from other areas--employment and income growth rates exceeded those of the nation, and the unemployment rate approximated the U.S. average. This combination of factors contributed to the change in the components of population growth in Lousiana.

When the Change Occurred

It has been an unwritten hypothesis by many demographic scholars in Louisiana that the change in the trend in the state's population growth actually occurred about 1974, in response to increases in the price of petroleum. An examination of the intercensal population estimates for the state reveals a jump in the annual increase since that year. Table 3 highlights the components of population change from 1970 to 1980. From 1974 to 1980, the growth averaged a stable 64,000 persons per year, compared to only 30,000 persons per year from

1970 to 1974. Nearly 77% of the decade's increase occurred from 1974 to 1980. Although natural increase (births minus deaths) is still by far the most prominent component of population change in Louisiana, it yields a relatively constant average growth of 38,000 each each year. It can be seen that the shift since 1974 is largely due to a change in net migration patterns in the state. In the first four years in the decade, Louisiana experienced a net outmigration of 28,000 persons. The following six years saw an unprecedented net inmigration into the state of 153,000 persons. It appears that 1974 did, indeed, mark the change in trend of net migration and population growth in Louisiana.

An analysis of economic times series reveals similar changes. Louisiana's employment, real earned income (i.e., adjusted for inflation), and real per capita personal income all showed increased growth rates after 1975 which were faster than the nation's rates of increase. Table 4 contains the corresponding data. It is hypothesized that some of this caused and some was caused by the observed change in net migration.

Table 4

Percent Change in Earned Income, Employment,
and Per Capita Personal Income,
Louisiana and the United States
1975-1980

	Louisiana	United States
Real Earned Income	33.9%	17.5%
Employment	19.6	14.9
Real Per Capita Personal Income	24.4	14.3

Source: U.S. Department of Commerce, Bureau of Economic Analysis, Regional Economics Information System, unpublished data.

The relationship between migration and economic conditions is a spiraling one -- migration into an area already enjoying favorable economic opportunities results in increased employment and earnings being generated, which, in turn, make the area even more attractive and incite more inmigration. The opposite case is true of outmigration from an area of declining economic opportunities. However, these phenomena are not indefinite and will ultimately stabilize or entirely reverse.

It is reasonable from the above explanation that an increase in the trend of net migration in 1974 is also reflected by corresponding changes in the trends of employment and earnings in the following year. There is a certain amount of lag between entering an area, finding employment in the area, and being recognized by government statistics as a productive member of the area's economy. Table 5 indicates that this is true. Each of the Louisiana economic time series exhibited increased annual changes after 1975.

A cursory examination of the relationship between net migration and changes in earned income, employment, and per capita personal income substantiates the hypothesis that net migration helps to drive the economy of an area. Table 6 contains the coefficients of correlation between 1970-1980 Louisiana annual net migration led by one year and the annual changes in each of the three economic time series. Note that the annual changes in each of the economic time series are highly correlated in a positive way with the net migration of the previous period. Both real earned income and employment correlation coefficients with net net migration are statistically significant at the 5% level; real per capita personal income is significant at the 10% level. But it may be hypothesized that Louisiana's net migration actually did impact Louisiana's economy, with the effect being reflected in the following year's economic statistics.

Table 5

Louisiana Annual Net Migration and Changes
in Earned Income, Employment, and
Per Capita Personal Income

If it is true as expected that the inmigrants into the state had greater earning power than the average Louisianian, an increase in inmigration should have resulted in increased per capita and median earned income. If the inmigrants had earning powers equal to the state average or median, per capita or median income would remain the same; if higher than the average, the per capita or median figure would increase; and if lower than the average, the per capita or median figure would decrease. As seen in Table 5, real per capita personal and earned income did rise substantially in the late 1970s, implying that the inmigrants into Louisiana in the last half of the 1970s may have earned wages higher than the state's average.

It is interesting to note the countercyclical nature of net migration into Louisiana since 1974. After the Arab oil embargo and subsequent oil price spirals, the world economy has been transformed in a fundamental way. A population trend change in the latter half of the decade in the state (which was observed to have been attributable mainly to a net migration trend change) was greater in times of national recession and less in times of national economic recovery. This phenomenon may be due to the combination of petroleum dependence of the Louisiana economy and its relative lack of cyclically sensitive durable goods manufacturing. When jobs became scarce elsewhere, the uniquely stable state economy was seen as an attractive force behind migrating. When economic conditions improved elsewhere, Louisiana's economic opportunities became relatively less attractive. This concurs with other findings that: "Observed net migration losses of depressed areas generally reflect low inmigration but not high outmigration, and the net migration gains of prosperous areas reflect high inmigration rather than low outmigration." [6]

[6] Ira S. Lowry, Migration and Metropolitan Growth: Two Analytical Models, Chandler, 1966, p. 32.

Migration by Race, Sex, and Age

The propensity to migrate is, in part, a function of a person's race, age, and sex. An examination of net migration by race gives insights into the racial nature of that shift. Table 7 shows decennial net migration by race from 1870 to 1980. White/other races' net inmigration achieved the highest level in measurable history, while black net outmigration was at its lowest level since the 1940s.

The direction of net migration for each race remained constant over the last three decades. Whites/others had positive net migration each decade. Blacks exhibited negative net migration each decade. But relative to other states, Louisiana has become more attractive to both whites/others and blacks than it was in the recent past. In previous decades, black net outmigration overshadowed white net inmigration, resulting in total net outmigration from the state. But that pattern was reversed in the 1970s. White/other net inmigration rose dramatically from 33,012 persons in the 1960s to 194,898 persons in the 1970s. At the same time black net outmigration dropped substantially from -139,824 to -68,891 persons. Consequently, total net migration for the state turned around from -106,811 persons to +126,007. These factors resulted in Louisiana having the greatest decennial net inmigration of persons in measurable history. The major cause for this reversal lies in increased white/other races net inmigration rather than in the reduced black net outmigration. The implication behind this observation is that, while economic opportunities in the 1970s increased for both groups, opportunities for blacks were still insufficient to deter them from seeking advancement elsewhere.

Graphs 1 through 9 depict the race/age/sex rates of net migration in Louisiana for the past two decades. Graph 1 reveals that, in total, nearly each five-year age group experienced net inmigration in the 1970s. The three exceptions to this are the 0-4, 25-29, and 75+ age groups. This pattern represents a marked contrast from the 1960-1970 period in which each age grouping lost population through

Table 7

Louisiana Net Migration by Race
1870-1980

Decade	Total		White/Other*		Black*

*Figures for decades from 1870 to 1960 are for whites and Negroes. 1960-1970 breakdowns pertain to whites and nonwhites.

Sources: Wrighton, Fred M. and Denton, Barbara H., "Net Migration in Louisiana," The Louisiana Economy, Vol. V, No. 1, August, 1971, Division of Business and Economic Research, Louisiana Tech University; Christou, Georgios C., Migration in Louisiana, Research Study No. 17, 1973, Division of Business and Economic Research, Louisiana State University in New Orleans; and Division of Business and Economic Research, University of New Orleans tabulations.

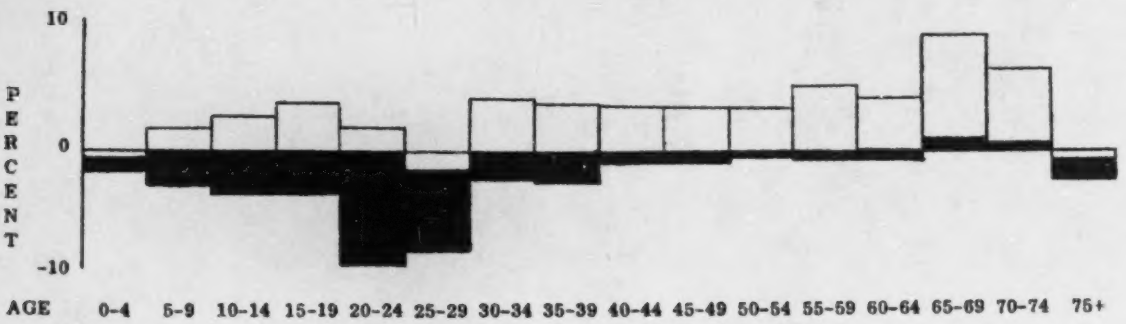
net migration. Even in those three age groups which had negative net migration in the 1970s, the rates of net outmigration declined substantially from those of the previous decade. In general, the entire curve for the 1970s seems to be shifted upward from that of the 1960s, but by varying degrees depending upon the age group.

In total, the net migration patterns for Louisiana in the 1970s appear to belie the traditional beliefs that migration rates are usually highest for persons in their twenties who move to start or enhance careers. But an examination of Graphs 2 and 3 which present race/age-specific migration rates uncovers the reasons behind this observation. For both the white/other and black race groups, persons in their twenties do have the highest tendency to migrate. For whites/others, the net migration is positive, and for blacks it is negative. Therefore, in net, the large gross streams cancel out one another and result in low net migration rates for the twenties age groups.

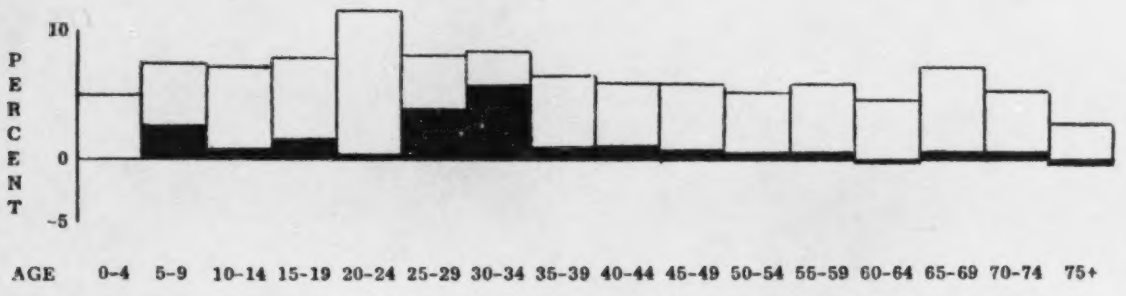
Louisiana's white/others group experienced net inmigration in the 1970s in all five-year age groups. The peak rate was in the 20-24 age category (11.6%) while the lowest rate was in the 75+ group (2.7%). Additionally, each age group increased its rate of net migration substantially compared to the 1960s. In general, the 1970s net migration rates for white/other races in total were remarkably consistent over all age categories.

The net migration patterns for Louisiana'a males and females were quite similar for the 1960s and for the 1970s. Graphs 4 and 5 present net migration rates by sex for those periods. From 1960 to 1970 the total male net migration rate was -2.6%, for females it was -3.0%. The comparable figures for the latter decade were 2.8% and 3.3% respectively. Females contributed slightly more towards the turn around in net migration than did males.

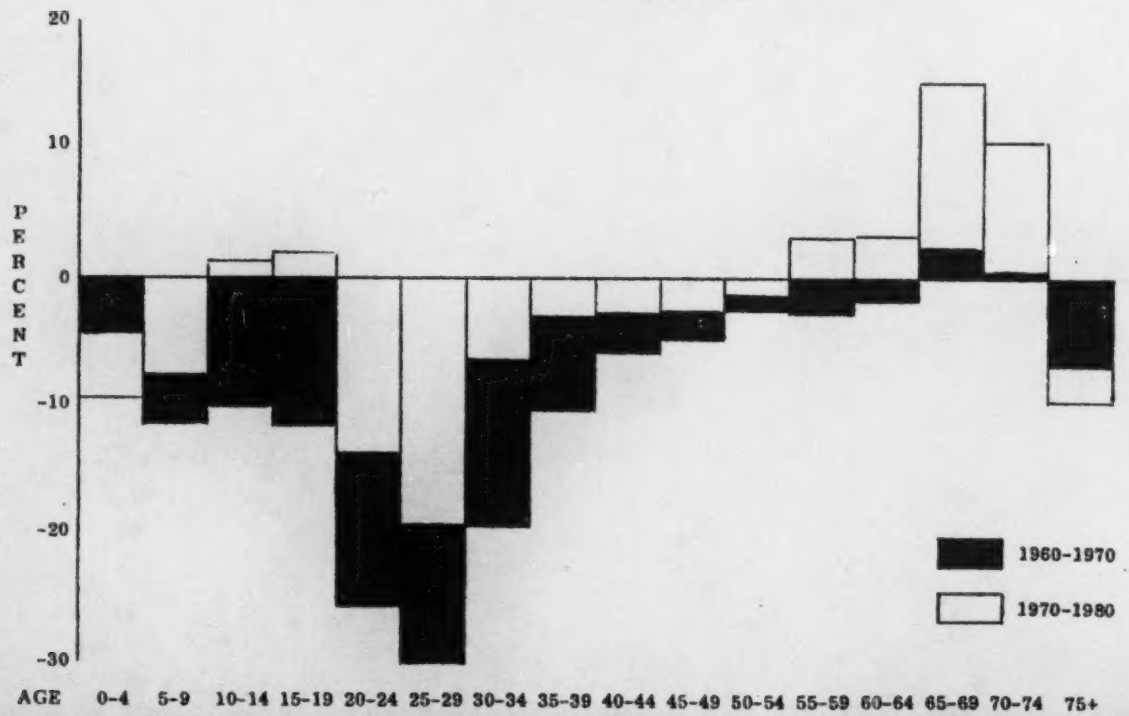
GRAPH 1. LOUISIANA TOTAL NET MIGRATION RATES BY AGE, 1960-1970 AND 1970-1980



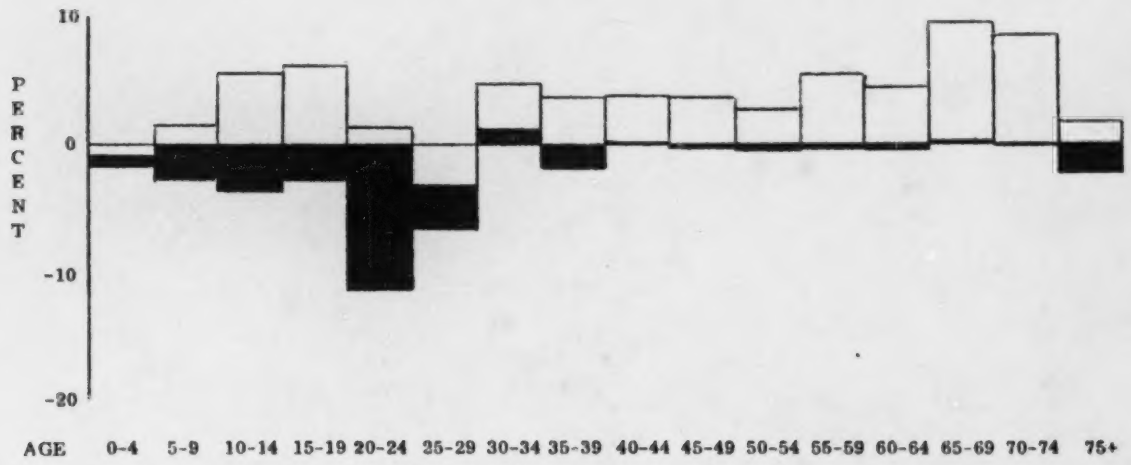
GRAPH 2. LOUISIANA WHITE AND OTHER NET MIGRATION RATES BY AGE, 1960-1970 AND 1970-1980



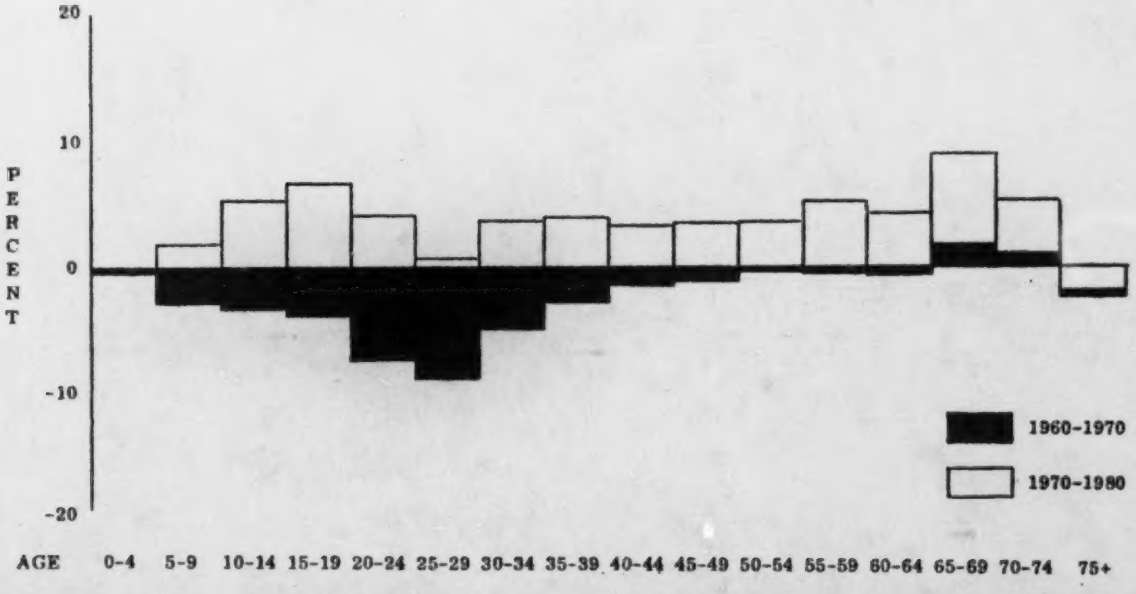
GRAPH 3. LOUISIANA BLACK NET MIGRATION RATES BY AGE, 1960-1970 AND 1970-1980



GRAPH 4. LOUISIANA MALE NET MIGRATION RATES BY AGE, 1960-1970 & 1970-1980



GRAPH 5. LOUISIANA FEMALE NET MIGRATION RATES BY AGE, 1960-1970 & 1970-1980



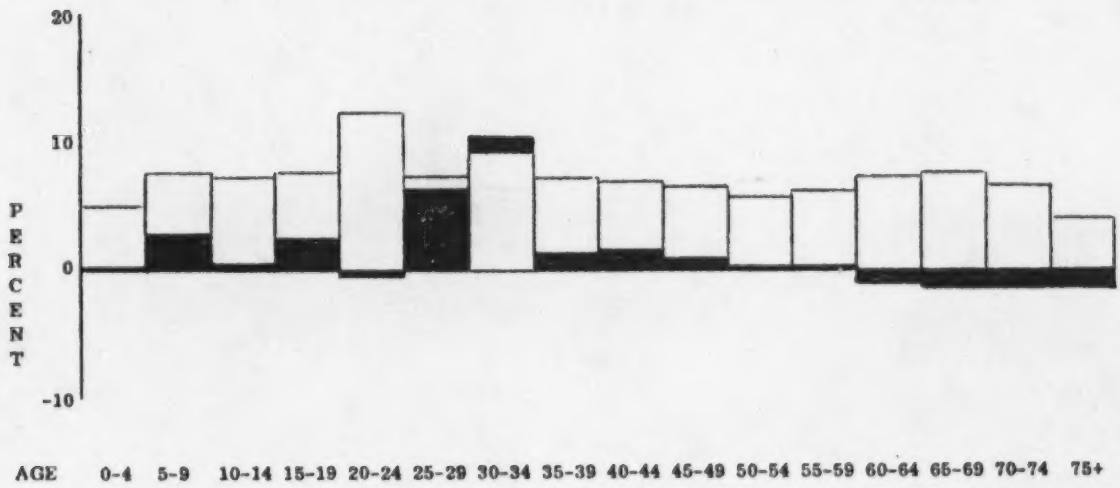
Net migration of the sexes with respect to age was also remarkably similar for each ten-year period. Both groups experienced net outmigration in the 1960s in nearly all five-year age groups. Only three female and two male age groups had net inmigration. In the 1970s nearly all five-year cohorts experienced net inmigration of both males and females. Only two male and two female cohorts had net outmigration.

The net migration rates for males and females by age grew even closer from the 1960s to the 1970s. From 1960 to 1970 seven age groups had net migration rate differences of 1.0% or more. That was reduced to only four in the next decade. In general, the patterns of net migration in Louisiana yield no real difference with respect to sex. Race is a much greater factor in the determination of net migration in the state.

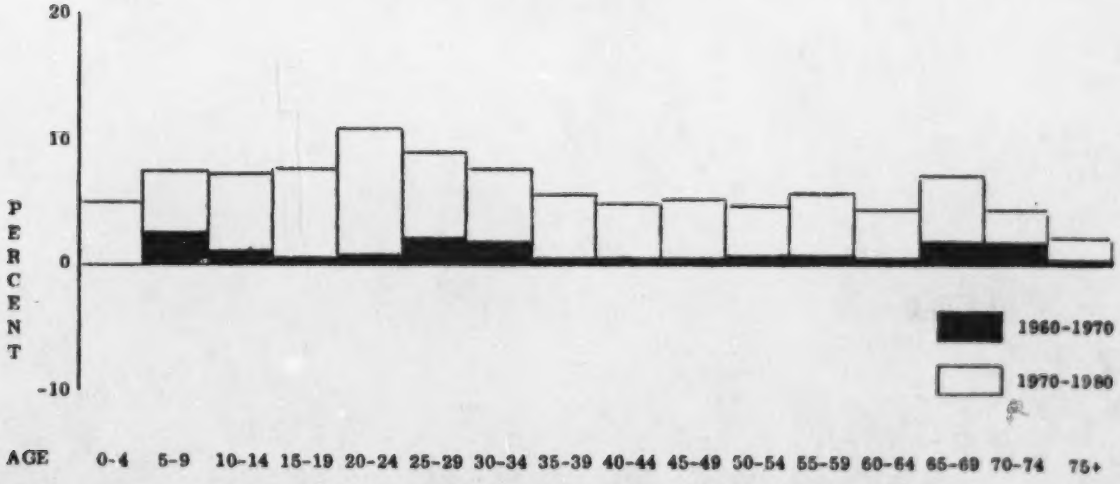
Graphs 6 and 7 show that the 1970-1980 net migration rates for both whites and other males and females were positive at all age levels. In contrast, males in some age groups, particularly the elderly, experienced net outmigration during 1960-1970. With the lone exception of males 35-39 years, each age group for both sexes increased its rates of net migration between the 1960s and the 1970s. The peak age group for net migration was 20-24 for both males and females (12.2% and 10.8%, respectively). In the 1960s, this age group for both sexes had near zero migration rates, a likely reflection of offsetting migration flows. In fact, in net terms 20-24 year old men left Louisiana in the previous decade.

Migration rates from 1970 to 1980 for Louisiana's white/other males and females are all very similar with respect to age. The two curves run nearly in parallel. The largest differential between the two sexes in any five-year age cohort was only 1.7%. Men had somewhat higher rates of net inmigration than their female counterparts. This is predictable, since more men than women participate in the labor force. The overall rate for males was 7.5%, and for females was 6.6%. These figures were well above the corresponding rates from the 1960s

GRAPH 6. LOUISIANA WHITE AND OTHER MALE NET MIGRATION BY AGE, 1960-1970 AND 1970-1980



GRAPH 7. LOUISIANA WHITE AND OTHER FEMALE NET MIGRATION RATES BY AGE, 1960-1970 AND 1970-1980



(1.6% and 1.0%, respectively). The rates for males equaled or exceeded those of females for each age group except two--15-19 and 25-29 years.

Net migration patterns in the 1970s for Louisiana suggest that economic opportunities were abundant for white/other races of all ages for both sexes. Better opportunities were available for both young career-starting and older career-advancing individuals. In addition, the state attracted elderly persons. This group normally moves either to be closer to friends and/or relatives or to retire. They may be newcomers to the state or natives returning to their birthplace. These factors all reflect a marked change in Louisiana's population and economic growth in the decade of the 1970s.

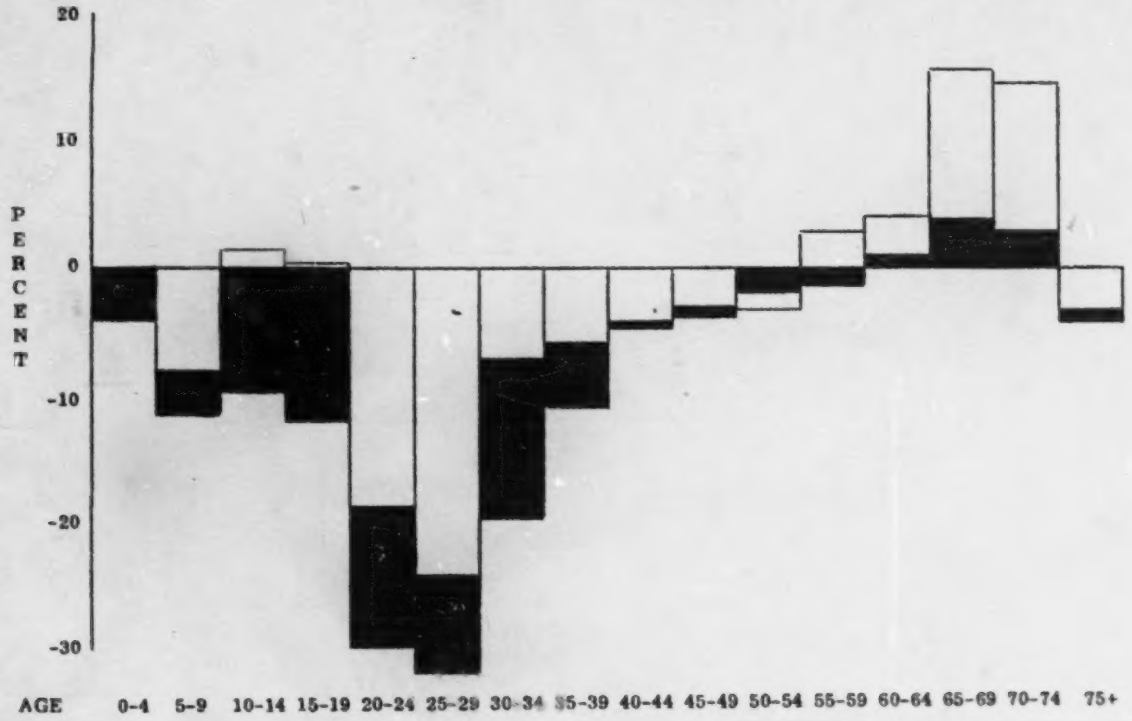
Changes in black net migration from the 1960s to the 1970s were presented in Graph 3. The 1970s brought improvements in net migration (including the reversal of negative to positive for 4 cohorts) for blacks in all age groups except the very youngest and oldest. However, there was still substantial net outmigration in all the primary work force age groups from 20 to 54 years. The peak age group for net outmigration was 25-29 years (-19.2%). As in the 1960s, the twenties was, by far, the most prominent age class to lose blacks through net migration. These factors point up the continued lack of opportunities for blacks in Louisiana -- particularly for career-starting individuals, but for career-advancing persons too. There was also a loss through net migration of children under 10 years who accompanied their parents to other states.

An aberration from the normal pattern of age-related net migration was found in the blacks 10-14 and 15-19 years of age. These two groups had net inmigration in the 1970s without a corresponding net inmigration in what would be expected to be their parents' age groups. One possible explanation for this is that those blacks in the career-advancing ages who moved to Louisiana (although fewer in number) had more children than those who moved out of the state. Unfortunately it is neither within the scope nor the capability of this study to further examine this unique occurrence.

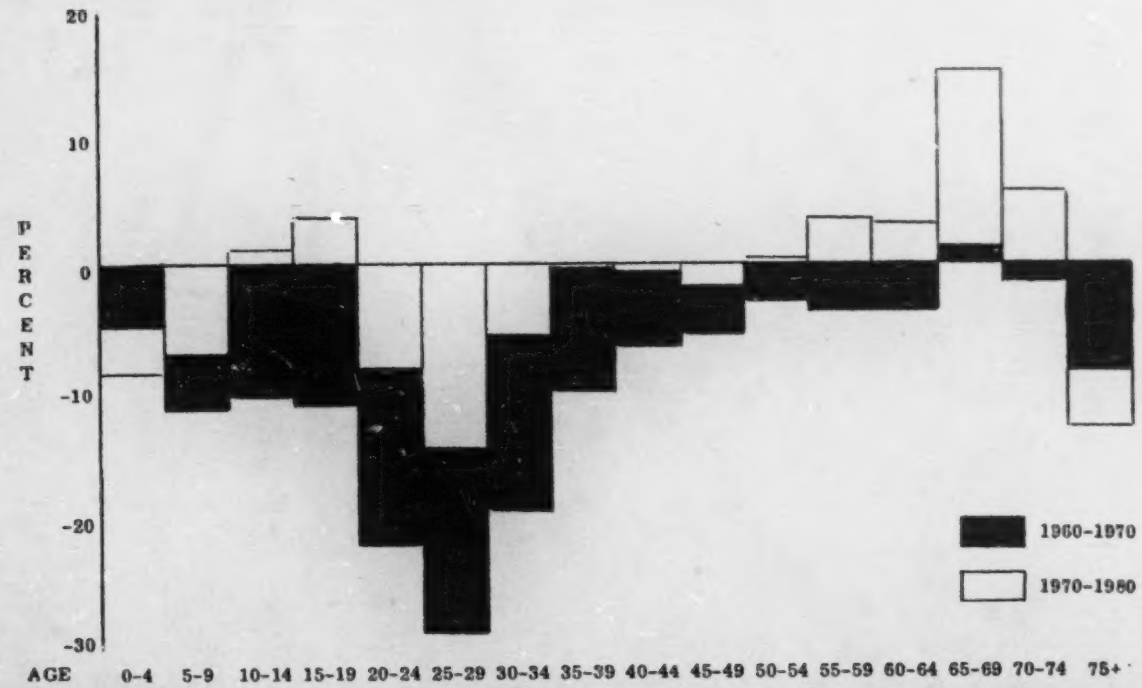
It is also striking to note the extremely large rates of net inmigration of blacks in the 65-69 and 70-74 year cohorts. Whites and others exhibited a similar pattern but to a lesser degree. This phenomenon can be partially attributed to the return to the state of natives who had terminated their careers elsewhere. The incidence of this happening is becoming increasingly more frequent throughout the South. In addition, there has been a redirection of blacks from rural southern areas to southern cities rather than to northern cities. Another hypothesis regarding these age groups may account for much of this abnormal occurrence. A great many people tend to understate their age. After all, youth is a prized but fleeting commodity and there is no real stimulus to report one's true age. But after reaching 65 years, there is a real incentive to reveal one's true age. At that point they qualify for Medicare, Social Security, and a whole raft of old-age benefits. The individuals 65-74 years of age in 1980 were not entitled to these benefits in 1970. Therefore it is quite possible that a number of these people who understated their age in the 1970 Census reported it correctly in 1980. As such, these individuals would be included in the residual calculation of net migration for the 65-74 age categories and not in the 55-64 group as would be expected. Therefore the 65-69 and 70-74 age groups net migration figures would be artificially inflated. It is not certain to what degree this hypothesis applies. Without primary data to analyze, it is impossible to tell accurately, but it appears that it may be a substantial factor.

The 1970s net migration patterns by age for black males and females were similar in direction to those observed for white/other races. As seen in Graphs 8 and 9, their migration rates were more divergent, however. Men had a total net migration rate of -7.0%, twice that of women (-3.5%). Both were significantly above the corresponding 1960s rates (-11.6% and -11.0%, respectively). Both sexes experienced net outmigration in total and at all age levels except 10-19 and 50-74 years. Additionally, both sexes showed increases from 1960's rates for every age group. Both males and females had the greatest net outmigration rates in the 25-29 and 20-24

GRAPH 8. LOUISIANA BLACK MALE MIGRATION RATES BY AGE, 1960-1970 AND 1970-1980



GRAPH 9. LOUISIANA BLACK FEMALE NET MIGRATION RATES BY AGE, 1960-1970 AND 1970-1980



age classes and the highest net inmigration rates in the 65-69 and 70-74 cohorts. Again, the two migration rate curves nearly parallel one another.

Once more, Louisiana's 1970s net migration rates suggest that economic opportunities for blacks continued to be poor. This is particularly true for younger individuals in the career-starting ages, which impacts men more than women. Although some improvement has been made, blacks are still far from experiencing the kind of economic progress that whites/others have enjoyed.

Chapter 5

NET MIGRATION BY REGION

The state of Louisiana can be viewed as being composed of eight different and distinct subeconomies, each of which is composed of a metropolitan center and related nonmetropolitan parishes. These regions are portrayed in Map 3 and Table 8.

The heart of each region is the Metropolitan Statistical Area (MSA), which includes one or more than one parish. Within each MSA, one or more parishes contain the central city(ies) for the area. These parishes will be referred to as "central parishes." The balance of the parishes in the MSA comprise the "metropolitan ring." Not all regions have metropolitan rings. Those whose central parishes comprise the entire metropolitan area will not have this ring. Lastly, the parishes not contained within the MSA definitions but still closely linked to the central parish(es) and metro ring make up the "nonmetropolitan fringe."

Identification of a parish grouping as an economic entity implies that the patterns of economic production, exchange, distribution, and consumption within each of the parishes are related in a complementary way to what takes place in the other parishes constituting its region.

In 1973 an Executive Order from the Governor of Louisiana created eight State Planning Districts designed to take better advantage of federal funds dedicated for local planning and development. Those districts were largely drawn along boundaries established for federal Economic Development Districts by the Economic Development Agency. As such they were seen to delineate the subeconomies of the state. But just as metropolitan areas can change over time as population shifts, so too can economic areas change as commerce and industry patterns shift. Parishes once thought to be economically linked to one central city have become more closely related to another.

The State Planning Districts and economic regions are similar, however. In fact, in two instances State Planning Districts and economic regions coincide. The areas surrounding Alexandria and Lake Charles have maintained relative economic consistency over time with their central cities. But, in general, it is our contention that the State Planning and Development Districts no longer capture the economic interrelationships of Louisiana'a subeconomies. We feel that the eight economic regions we have defined do that more effectively.

Since it has been shown that migration is generally economically related, we shall focus our regional analysis of net migration on our economic regions rather than on State Planning Districts. Because these regions have only been recently devised, no comparable migration data for the 1960s are available. Consequently the discussion of these areas will be limited to the 1970s. But since the economic regions and State Planning Districts are geographically similar, some general observations can be made between the two decades. Note that the age/race/sex detailed net migration data for both economic regions and state planning districts from 1970 to 1980 are included in the Volume 2 report of this series.

An examination of net migration by economic region reveals the areas of relative economic strength and weakness. Table 9 contains net migration for Louisiana's economic regions. The 1970-1980 figures suggest that all areas of the state performed relatively well. Each of the eight economic regions had positive net migration in the decade.' The Baton Rouge region had by far the largest net inmigration of any region. Roughly 50% of all net inmigrants to Louisiana settled in the Baton Rouge area.

The petroleum boom in the state may have attracted many of these inmigrants. This fact seems to hold true for the entire southern half of the state. The area from New Orleans to Lake Charles, which is where Louisiana's petroleum and related industries are concentrated, accounted for 89% of all the net migration into Louisiana in the 1970s. In addition to its location in Louisiana's oil patch, Baton Rouge was the center of state government.

Table 9

Louisiana Net Migration by Economic Region
1970-1980

Economic Region	Total		White/Other		Black

Shreveport remains the shining star in the north Louisiana economy. It is the only north Louisiana region which attracted any substantial net inmigration. The Alexandria and Monroe regions had rather negligible overall net inmigration. These facts indicate that the agriculture and forestry based economies in the 1970s fared worse than the petroleum and manufacturing based areas.

Race-specific net migration patterns remained relatively consistent across economic regions. The general pattern holds true throughout Louisiana that economic opportunities in the 1970 were more abundant for whites. Each region had considerable net inmigration of whites and others and all except Baton Rouge had substantial outmigration of blacks. The singular distinguishing characteristic of Baton Rouge is that it is the seat of state government. This fact may have been the force behind the net inmigration of blacks into the Baton Rouge region.

In a sense, the black net outmigration represented a change in historical trend. In the 1970s most regions experienced reduced net outmigration of blacks. But the outmigration was spread throughout the state's regions. In fact, the two regions with the greatest rates of black outmigration (Lafayette and Houma-Thibodaux) were the areas presumed to enjoy the most prosperity from the petroleum boom in the 1970s. It appears that blacks did not participate in the petroleum economic expansion nearly as much as whites/others.

In contrast, black net outmigration in the 1960s was more concentrated in a smaller section of the state. As Wrighton and Denton had noted:

> The greatest incidence of net migration is, for the most part, localized in the northeast corner of the state. There is a clearly defined geographic character to net migration, with the northern half of the state experiencing a more intensive outmigration than in the southern half. This difference is partially explained by the

predominance of rural parishes in north Louisiana which appear to be more susceptible to a condition of net outmigration.[7]

It is clear that predominately rural economic regions performed worse than the more industrialized areas of Louisiana in the 1970s, yet black outmigration in those areas declined from the 1960s to the 1970s. One reason for this relates to exhaustion of the migrant pool. After many years of substantial outmigration, the pool of potential outmigrants may have been largely depleted. In effect, most of those people who might have left had already done so. In addition, the redistribution and return characteristics of migration in the South as a whole may have stabilized net migration in those rural areas.

Net Migration in Central Parishes

It has been the national trend for many years that larger cities have experienced net outmigration of population, with suburban areas and smaller cities receiving these movers. It is not possible to accurately measure net migration in central cities in Louisiana because the data pertain only to parishes. Only in the case of New Orleans whose city and parish are coterminous can this type of analysis be performed. Despite this limitation, an indication of the movement in the central cities can be obtained from the net migration for economic region central parishes in Table 10.

Sources: U.S. Bureau of the Census; 1970 and 1980 Censuses of Population and Housing, General Population Characteristics; Louisiana Department of Health and Human Resources, Office of Health Services and Environmental Quality, unpublished data; and Division of Business and Economic Research, University of New Orleans tabulations.

As a whole, Louisiana's central city parishes lost population in the 1970s through the net migration process. The dominant force behind this exodus is the massive net outmigration from Orleans Parish. Shreveport's central parish (Caddo) was the only other in the state to have negative net migration, but by a more moderate degree. The central parishes of the Baton Rouge (East Baton Rouge) and Lafayette (Lafayette) regions both experienced substantial net inmigration. All the other economic regions have significantly smaller numbers of net inmigrants.

With respect to race, the central parishes were net recipients of white/other net migrants. Orleans Parish stands alone as the only central city parish to experience a net outmigration of white/other races. This net outmigration was so extensive that it cancelled out nearly all the net inmigration from the other regions central parishes so that the state total was minimal. This fact represents a continuation of a trend of white flight from Orleans Parish that began in the 1960s. The Baton Rouge and Lafayette central parishes attracted the most white/other net migrants.

Louisiana's central parishes as a whole lost blacks in the 1970s through net migration. Orleans Parish was once more the largest affected. In fact, the New Orleans region was the only one to have net outmigration from its central parish of both whites and others and blacks. It can been seen that New Orleans does mirror the characteristics of the nation's older and larger cities in this respect.

Black net migration in the central parishes of the state's other economic regions was mixed. East Baton Rouge Parish had by far the largest net inmigration of blacks.

Louisiana seems to follow the national trend of net outmigration from large cities (i.e., New Orleans) and net inmigration into smaller ones. White/other races were more prone to migrate into central parishes than blacks. In all regions but New Orleans, white/other net migration exceeded that of blacks.

Net Migration in Metropolitan Ring Parishes

As cities grow, there is an increased tendency towards suburbanization. This scenario seems also to apply to Louisiana. Table 11 presents net migration for the metropolitan ring parishes in the state.

In summary, it can be seen that suburbanization is the dominant factor influencing population growth in Louisiana. Metropolitan rings in Louisiana attracted substantial net inmigrants from 1970 to 1980. The New Orleans region was the largest recipient of these these persons. Nearly 79% of all net migrants to the state's metro ring parishes settled in the New Orleans area. The remaining metropolitan rings each had positive net migration in lesser numbers.

All the metro rings also experienced net inmigration of white/other races. The New Orleans area was again the leader in this category. In addition, New Orleans was the only economic region to have net inmigration of blacks into its metropolitan ring. The New Orleans metropolitan area clearly portrays a scenario of suburbanization of all racial groups. In contrast, in the Baton Rouge region, the central parish drew black migrants away from the metropolitan ring. Due solely to the net inmigration of blacks into the New Orleans metro ring, Louisiana, in total, had positive net migration of blacks into metropolitan ring parishes.

Net Migration in Nonmetropolitan Fringe Parishes

Population growth in the United States in the 1970s, in percentage terms, was greatest in nonmetropolitan areas. This change in trend towards "exurbanization" has been fueled by improved transportation facilities which increase commuting range to cities; the economies gained by moving industry from central cities to ring and fringe areas; and the tastes and preferences for living in small town and/or rural environments. However as seen in Table 12, this process has not yet fully caught hold in Louisiana's nonmetropolitan areas.

Louisiana's nonmetro fringes, in total, lost population through net migration in the 1970s. In this respect, Louisiana is totally unlike the balance of the country in its exurbanization tendencies. The distribution by economic region was varied. Five regions had negative net migration while the other three had postitive net migration. The Shreveport fringe area was the largest gainer; Lafayette's fringe was the largest loser. There appears to be no set pattern between economic regions with respect to net migration in the nonmetropolitan fringe areas.

Whites/others were generally attracted to Louisiana's nonmetro areas. Only the Houma-Thibodaux and New Orleans regions experienced net outmigration of this race group. The Shreveport and Baton Rouge areas had the largest number of net inmigrants.

Blacks continued to outmigrate, in net, from the state's nonmetro areas. Each economic region had negative net migration of blacks from 1970 to 1980. The Monroe and Lafayette regions lost the most blacks through this process. In the 1960s, black net outmigration was highly concentrated in the Monroe area. But in the 1970s it was spread throughout the entire state.

Table 12

Louisiana Net Migration by Nonmetropolitan Fringe Parishes of Economic Regions 1970-1980

Economic Region	Total		White/Other		Black	
	Number	Rate	Number	Rate	Number	Rate

The trend that rural parishes are more susceptible to net outmigration of blacks is still a major factor influencing population change in Louisiana. Some of the reasons for this are the decline in sugar and rice production in the state and the increased tendency towards oligopoly and mechanization in the agricultural sector in the state in the 1970s. These forces diminished the opportunites for blacks who had traditionally been employed in agriculture. This trend of black outmigration from rural areas is continuing, but at a decreased rate. As stated earlier, there may be a depletion factor which contributed to this slowdown.

To recap, each economic region in Louisiana enjoyed net inmigration of population from 1970 to 1980. The vast majority of this net inmigration went to metropolitan ring areas. Central parishes, as a whole, lost population through net migration, due almost totally to the overwhelming net outmigration from the state's most populous parish, Orleans. Nonmetropolitan fringe areas lost the most population through net migration, reflecting the decreased importance of farming to the state's economy.

The white/other race group had positive inmigration into all types of economic region component areas. Metro fringe areas were the most attractive for white/other net inmigrants, followed by nonmetro fringe areas, and lastly by central city parishes. This pattern is similar to that experienced in the decade throughout the United States.

Blacks had slight net inmigration into metropolitan fringe areas, due primarily to the New Orleans region. In central city parishes, they had slight net outmigration. But the largest amount of net outmigration of blacks came from the predominantly rural nonmetropolitan fringe areas of the state's economic regions. This fact was expected, since agriculture has declined in relative economic significance throughout Louisiana. As a result, the employment opportunities for blacks who had traditionally worked the farms became severely limited and forced emigrants to seek suitable employment elsewhere.

Net Migration by Parish

It is not within the scope of this study to attempt to explain net migration for every parish in Louisiana. But since migration varies considerably across parishes, we shall mention some of the more prominent cases. Maps 4-9 and Tables 13-15 present the net migration figures of parishes for the past two decades.

Net migration, in absolute terms, is, of course, directly related to population change. Yet it is also useful to examine the rates of net migration. For example, small parishes would not be expected to have much absolute net migration, either positive or negative, but may have net migration rates that are quite high. In cases of this type, the rates may be better indicators of the nature of population change.

Some Changes Can be Observed From the 1960s to the 1970s

From 1960 to 1970, only 13 of Louisiana's 64 parishes had net inmigration, as seen in Map 4. In the 1970s, the number jumped up to 32 parishes, portrayed in Map 5. In addition, all but two of the parishes experiencing net inmigration in the earlier period were in the southern half of the state. One of those was Vernon Parish, whose inmigration can be attributed to the military buildup at Fort Polk associated with the Vietnam War. In the 1970s, this phenomenon reversed and the parish had substantial net outmigration.

From Map 5, it can be seen that, in the 1970s, net inmigration spread to parishes throughout the state. Parishes with net outmigration were concentrated in the south central and extreme northeast portions of the state. Agricultural parishes along the Mississippi River continued to be exporters of net migrants.

Some consistencies can be observed from Tables 13. In both periods Jefferson Parish had the greatest net inmigration in the state, while Orleans Parish had the most net outmigration. St.

Source: Christou, Georgios C., Migraton Louisiana, Research Study No. 17, 1973 Division of Business and Economic Research, Louisiana State University in New Orleans; and U.S. Bureau of the Census; 1970 and 1980 Censuses of Population and Housing, General Population Characteristics; Louisiana Department of Health and Human Resources, Office of Health Services and Environmental Quality, unpublished data; and Division of Business and Economic Research, University of New Orleans tabulations.

Tammany and East Baton Rouge Parishes also were in the top five rankings in terms of net inmigration. Additionally, Caddo and St. Landry maintained their top five ranking of parishes with the largest net outmigration.

In percentage terms there is also consistency, particularly in net outmigration. In both decades the extreme northeast parishes rank highest in the rates of net outmigration. With respect to net inmigration, only St. Tammany and Livingston, the "bedroom community" parishes for New Orleans and Baton Rouge, respectively, rank high. The other parishes in the top five reflect relative economic booms.

From 1960 to 1970, 29 parishes had net inmigration of whites/others, as seen in Map 6. In the succeeding ten-year period, that number increased to 53 parishes, as portrayed in Map 7. Once again, Jefferson Parish led all others in both decades in net inmigration of whites, as seen in Table 14. Orleans also had the largest amount of net outmigration of whites/others in both periods. The patterns of total net migration largely mirror those of white/other migration. This is expected since net migration of whites contributes the most to total net migration.

With respect to net outmigration of whites/others, there is no real consistency outside of Orleans Parish. The parishes which had net outmigration in the 1970s had smaller absolute numbers than those of the 1960s.

The parishes of St. Tammany and Livingston remianed consistently high the rankings of net inmigration rates of whites/others. Again, these are the "bedroom" communities for the state's two largest cities. It is interesting to note the substantial 1970-1980 rates of net inmigration in Sabine and DeSoto Parishes. These two areas in the Shreveport region have been expanding their industrial base in the decade.

Source: Christou, Georgios C., Migration Louisiana, Research Study No. 17, 1973 Division of Business and Economic Research, Louisiana State University in New Orleans; and U.S. Bureau of the Census; 1970 and 1980 Censuses of Population and Housing, General Population Characteristics; Louisiana Department of Health and Human Resources, Office of Health Services and Environmental Quality, unpublished data; and Division of Business and Economic Research, University of New Orleans tabulations.

Orleans and East Carroll Parishes have been consistently high in the rates of net outmigration of the white/other group. They ranked first and second, respectively, in both decades. The other top ranking parsihes were largely rural.

In the 1960s, only five parishes had net inmigration of blacks, as seen in Map 8. From 1970 to 1980 the total was six as portrayed in Map 9. Jefferson and Vernon Parishes were the only two to be included in both periods. In addition, the magnitude of black net migration in those parishes with net inmigration grew substantially.

On the net outmigration side, the northeastern parishes again appear quite prominently, as presented in Table 15. Some surprises are encountered, however, particularly in the 1970s data. In that period both Plaquemines and St. Bernard Parishes entered into the top ranking areas of black rates of net outmigration.

Chapter 6

NET MIGRATION IN THE NEW ORLEANS ECONOMIC REGION

As by far the largest economic region in Louisiana, the New Orleans region has already entered into the discussion of migration across the states' regions. We propose now to take one further glance at the migration patterns within the New Orleans economic region.

The region has had moderate net inmigration over the past 20 years. In the 1960s, a net number of only 758 migrated into the area (see Table 16). By the next decade, that amount climbed to 26,290 persons (see Table 17). There has been a consistent pattern of white/other net inmigration and black outmigration. In fact, the black net outmigration in the 1970s exceeded that of the prior period. It is clear, therefore, that the increase in net inmigration into the New Orleans area is due solely to the increase in white/other races net inmigration. As in Louisiana, in general, economic opportunities in the New Orleans region have been more abundant for whites than for blacks.

The metropolitan ring area has been the only component of the region to experience net inmigration. Jefferson and St. Tammany Parishes were the most attractive parishes. Jefferson Parish had experienced the largest amount of net inmigration in the state in both ten-year periods, while St. Tammany Parish had the highest rate of net inmigration in the 1970s. In addition, the metro ring has had net inmigration of all race groups in the 1970s due mainly to the net inmigration of blacks into Jefferson Parish.

The nonmetro fringe parishes have been exporters of net migrants since 1960. Again, blacks have been more susceptible to emigrate, but in slightly declining numbers.

Orleans Parish has had the largest net outmigration of any parish in Louisiana. This is expected since it has the largest population in

the state. In this respect migration in New Orleans mirrors the national patterns. In addition, all race groups outmigrated, in net, in both decades.

Blacks actually increased in the number and rate of net outmigration in the 1970s. As hypothesized earlier, these individuals are probably the better educated and trained who have exhausted the search for prosperity in New Orleans compared to the opportunities which they found elsewhere.

In summary, the New Orleans economic region seems to have had sufficient economic opportunities to draw net inmigrants from other areas. These opportunities have been largely limited to white/other races, however, as blacks continue net outmigration from the area. Suburbanization is the greatest factor influencing population change in the New Orleans region. It is expected that this trend will continue for some time.
